# The Timber Resource of the Chippewa National Forest

**Neal P. Kingsley and Robert E. Brittain**

***Note:*** *Data from new forest inventories are often compared with data from earlier inventories to determine trends in forest resources. However, for the comparisons to be valid, the procedures used in the two inventories must be similar. As a result of our ongoing efforts to improve the efficiency and reliability of the inventory, several changes in procedures and definitions have occurred since 1980. Because some of these changes will make it inappropriate to directly compare the 1990 data with those published for 1980, data from the 1980 inventory have been reprocessed using the 1990 procedures. Please refer to the section labeled "Comparing Minnesota's Fifth Inventory with the Fourth Inventory" for more details.*

The Chippewa is the oldest of the Eastern Region's National Forests. In 1902, the Minnesota Federation of Women's Clubs secured passage of the Morris Act, protecting the area as a Forest Preserve. In 1908, President Theodore Roosevelt proclaimed this same area as the Minnesota National Forest. Later the name was changed to reflect the region's dominant Indian influence. Most of the Leech Lake Indian Reservation lies within the Forest's outer boundary. More than 5,000 cultural resource sites are believed to exist on the Chippewa. Managing these sites in cooperation with the Indian community is an integral part of managing this National Forest.

The Chippewa National Forest has been managed for more than 75 years under the multiple-use concept of forest management. This concept integrates all the Forest's resources—wildlife, water, recreation, cultural heritage, and timber. Wildlife, especially white tail deer, grouse, and many species of waterfowl abound. The Chippewa is home to one of the largest concentrations of bald eagles in the United States and to small populations of timber wolves and moose.

Water is everywhere on the Chippewa. More than 900 miles of rivers and streams and more than 162,000 acres of wetlands provide essential habitat for over 200 species of fish and wildlife including walleye pike, northern pike, eagles, ospreys, herons, loons, and many other wetland birds. The management and protection of this water resource are important functions of the Forest.

With an abundance of water, wildlife, and scenic beauty, the Chippewa is becoming an increasingly important recreational resource. The Forest provides campgrounds, picnic areas, boat launch sites, and trails for recreationists. In 1990, the Chippewa had an estimated 4.5 million recreation visitors.

In addition to providing wildlife habitat, watershed protection, recreational opportunities, and taking care of cultural treasures, the Chippewa has sold an average of 142,000 cords of wood annually over the past 10 years to Minnesota's forest-based industries. This report is about the Chippewa's role as a supplier of timber. Not all the volume and growth reported here is in fact

---

**Neal P. Kingsley**, Research Forester, received his bachelor's degree in forestry in 1961 and his master's degree in forest economics in 1963 from the University of New Hampshire. He spent 25 years with the Northeastern Forest Experiment Station before joining the North Central Forest Experiment Station in 1988 as Program Manager of the Forest Inventory and Analysis project.

**Robert E. Brittain** received his bachelor's degree in forest management from West Virginia University in 1961. He began his Forest Service career on the Chequamegon National Forest in Wisconsin. He worked on the Mark Twain and Monongahela National Forests before joining the staff of the Chippewa as a Forest Silviculturist in 1977.

available for timber harvesting. Because management of the Chippewa is guided by a comprehensive management plan, some areas are managed for non-timber benefits and others are not currently available for harvesting to allow them to develop into desired forest ecosystems.

### Forest Area

The Chippewa National Forest encompasses 662.9 thousand acres of land in north-central Minnesota. Nearly 88 percent of this land—581.6 thousand acres—is classed as forest land. Of this, 567.2 thousand acres is classed as timberland, forest land that is capable of producing a sustained crop of wood and that is not withdrawn from timber harvesting. Under the Forest's management plan, 480 thousand acres are considered suitable for harvesting.

The aspen forest type dominates the Chippewa's landscape, covering 42 percent of the Forest's timberland—238.6 thousand acres (fig. 1). Despite the predominance of aspen, the Forest still contains an impressive mix of species. However, no other forest type accounts for more than 10 percent of the Forest's area. The second most abundant type, maple-basswood, covers only 55.4 thousand acres. The third and fourth ranked types, red pine and black spruce, cover 51.3 and 37.5 thousand acres, respectively[1].

Timber on the Chippewa is maturing (fig. 2). In 1990, 40 percent—226.6 thousand acres—of the Forest's timberland was in sawtimber-size stands, up from 30 percent in 1980. Likewise, the area of poletimber stands declined from 45 to 29 percent—162.7 thousand acres. While there was more timberland in sawtimber-size stands in 1990 than in 1980, there was also more in seedling-sapling stands. The area of seedling-sapling stands was 177.8 thousand acres—31 percent of the timberland—up from 24 percent in 1980. This indicates that older stands are being replaced with younger, faster growing stands. When aspen stands mature, they decline very quickly as mortality begins to exceed growth. If this process is allowed to continue, these stands will become dominated by other species and the type will change. In

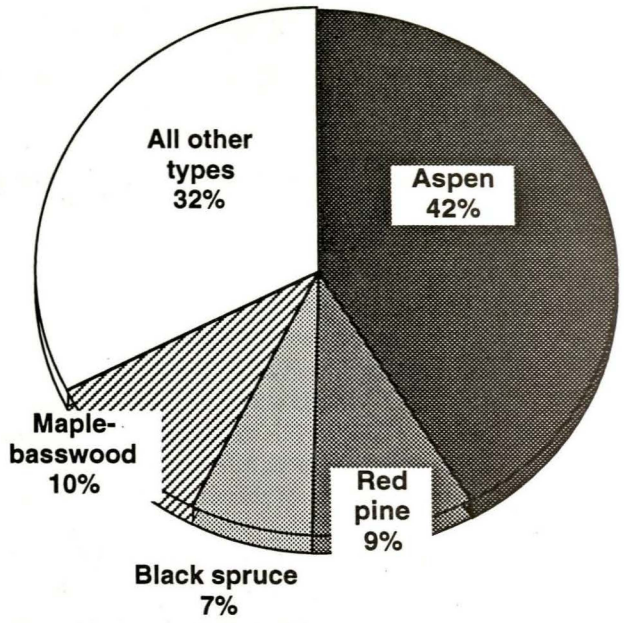

Figure 1.—*Area of timberland by major forest type, Chippewa National Forest, 1990.*

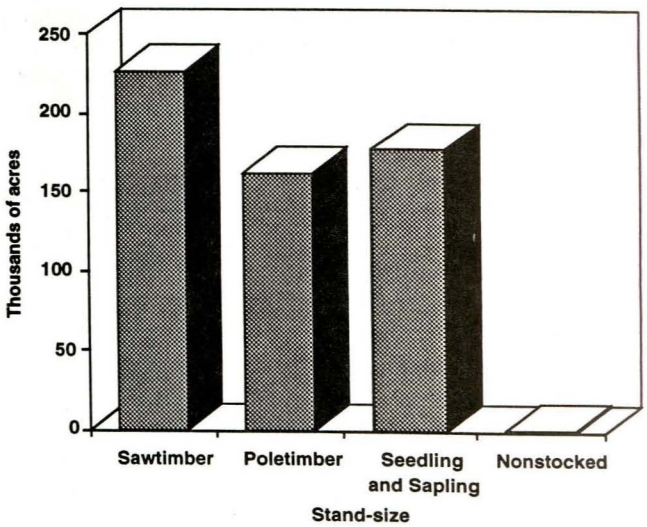

Figure 2.—*Area of timberland by stand-size class, Chippewa National Forest, 1990.*

[1]*Forest type in this inventory is determined in a different manner than in the Chippewa's stand examinations. For this reason, forest types may vary from those shown in the Forest's management plan.*

this region, this succession usually leads to maple-basswood or balsam fir stands, depending on the site. To maintain an abundance of aspen, an important timber and wildlife species, these older declining stands must be replaced with young stands of aspen before they change type. All in all, the distribution of stand-size classes in 1990 was better than in 1980.

### Timber Volume

Timber volume on the Chippewa increased by 9 percent since 1980 to just over 743 million cubic feet in 1990 (fig. 3). The Forest's most abundant species, quaking aspen, gained only 2 percent to 193.7 million cubic feet. However, the Forest's second most abundant species, red pine, increased 86 percent to 120.5 million cubic feet. Another important softwood, white pine, gained 46 percent to 25.3 million cubic feet. Black spruce showed a gain of 174 percent. However, most of this black spruce undoubtedly resulted from the reclassification of many wet sites from unproductive to marginally productive forest land.

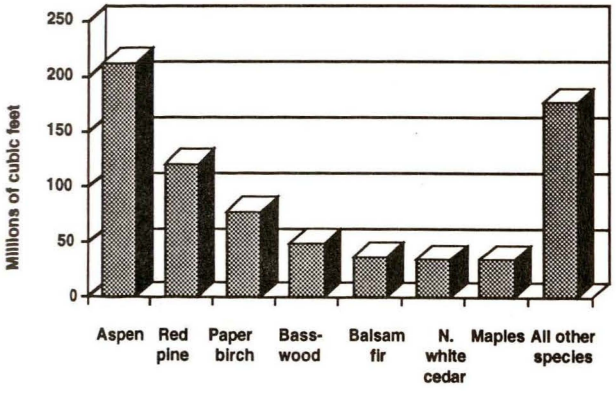

Figure 3.—*Volume of growing stock by major species, Chippewa National Forest, 1990.*

Overall, the total volume in hardwood species has remained essentially unchanged since 1980. The only major hardwood species to show a significant gain was basswood, which stood at 48.8 million cubic feet, up about 34 percent since the last inventory. Thus, it would appear that softwood species are becoming a more significant component of the Forest.

The volume of sawtimber on the Chippewa stood at 2.0 billion board feet, up 28 percent since 1980. The volume of aspen sawtimber, at 558 million board feet, was up 38 percent, reflecting maturity or overmaturity of many aspen stands. The volume of red and white pine sawtimber also showed significant increases. Red pine, at 521 million board feet, was up 58 percent. White pine, at 126.4 million board feet, was up 75 percent. Among the major hardwoods other than aspen, basswood showed the most significant gain with a rise of 77 percent to 119 million board feet.

### Timber Growth and Removals

Net annual growth on the Chippewa is slightly higher than in the surrounding region of the State. During the period 1980-1990, net annual growth averaged 19.2 million cubic feet or 33.8 cubic feet per acre of timberland (fig. 4). During this same period, the surrounding region averaged 28.4 cubic feet per acre per year. Thus, while net annual growth in the region averaged 2.2 percent of the average inventory, it averaged 2.7 percent on the Forest. Growing sites on the Chippewa are not significantly better than in the region as a whole. Therefore, the higher growth on the National Forest probably reflects a higher level of forest management there. Net annual growth of sawtimber averaged 81.5 million board feet or about 4.5 percent of the sawtimber inventory.

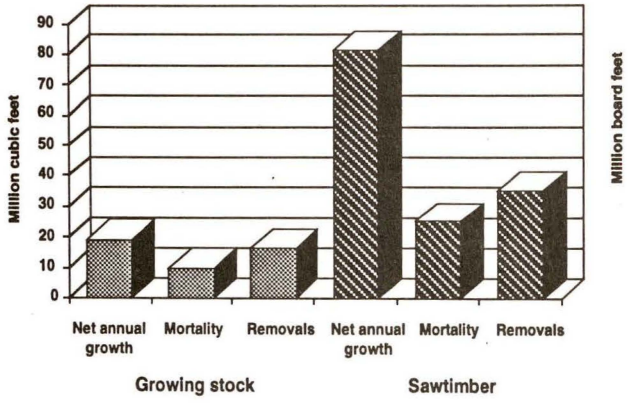

Figure 4.—*Volume of net annual growth, mortality, and removals, growing stock and sawtimber, Chippewa National Forest, 1990.*

Average annual removals of growing stock during the 1980-1990 period were just over 16 million cubic feet, about 2.3 percent of the average annual inventory and 85 percent of the net annual growth. Average annual removals of sawtimber present a somewhat different story that reflects the fiber versus saw-log economy of the region. Average annual removals of sawtimber from 1980 to 1990 were 35.3 million board feet, only 43 percent of the average net annual growth of sawtimber and slightly less than 2 percent of the sawtimber inventory. In a fiber-oriented forest economy, there is little premium for large trees.

During the 1980-1990 period, the mortality of growing stock averaged just under 10 million cubic feet, slightly more than half the average net annual growth. Mortality of sawtimber averaged 18 million board feet, less than half the average net annual growth of sawtimber.

Although the level of mortality of growing stock on the Chippewa is not excessively high, much of it can be traced to the high level of mortality of aspen and, to a lesser degree, of paper birch. Mortality of aspen growing stock, at 3.9 million cubic feet, averaged 76 percent of net annual growth. This reflects the high number of mature and overmature stands referred to earlier. When aspen stands reach maturity, they decline rapidly; mortality of aspen often exceeds growth as other species dominate the stand. To maintain aspen stands, it is necessary to harvest before they reach this stage so they can be replaced by young fast growing stands. That this is being done on the Chippewa is evidenced by the fact that removals of aspen averaged more than 8 million cubic feet during the period between inventories, 3 million in excess of net annual growth. We can expect to see a significant increase in aspen growth in the future as these older stands are harvested and regenerated. The situation for paper birch is similar. In the absence of strong markets for birch, many stands have reached the 70- to 80-year age class and have begun to decline.

## APPENDIX

### ACCURACY OF THE SURVEY

Forest Inventory and Analysis information is based on a sampling procedure designed to provide reliable statistics at the State and Survey Unit levels. Consequently, the reported figures are estimates only. A measure of reliability of these figures is given by sampling errors. These sampling errors mean that the chances are two out of three that if a 100-percent inventory had been taken, using the same methods, the results would have been within the limits indicated.

For example, the estimated growing-stock volume in the Chippewa National Forest in 1990, 743.2 million cubic feet, has a sampling error of ±3.70 percent (±27.5 million cubic feet). The growing-stock volume from a 100-percent inventory would be expected to fall between 715.7 and 770.7 million cubic feet (743.2 ± 27.5) there being a one in three chance that this is not the case.

The following tabulation shows the sampling errors for the Chippewa National Forest inventory:

| Item | Forest totals | Sampling error |
|---|---|---|
| Growing stock | (Million cubic feet) | (Percent) |
| Volume (1990) | 743.2 | 3.70 |
| Average annual growth (1980-1990) | 19.2 | 5.50 |
| Average annual removals (1980-1990) | 16.3 | 21.20 |
| Sawtimber | (Million board feet) | |
| Volume (1990) | 2,031.9 | 5.00 |
| Average annual growth (1980-1990) | 81.5 | 5.80 |
| Average annual removals (1980-1990) | 35.3 | 25.40 |
| Timberland area (1990) | (Thousand acres) 567.2 | 2.00 |

As survey data are broken down into sections smaller than Survey Unit totals, the sampling error increases. For example, the sampling error for timberland area in a particular county is higher than that for total timberland area on the Forest. This tabulation shows the sampling error for Forest totals. To use this information

for data smaller than Forest totals, compute error estimates with the following formula:

$$\text{Error} = \frac{(SE)\sqrt{\text{National Forest total area or volume}}}{\sqrt{\text{Volume or area smaller than national Forest total}}}$$

E = sampling error in percent
SE = National Forest total error for area or volume

For example, to compute the error on the volume of quaking aspen in the Forest, proceed as follows:

The total volume of quaking aspen in the Forest from table 8 = 193.7 million cubic feet

The total volume of all growing stock in the Forest from table 8 = 743.2 million cubic feet

The total error for growing-stock volume from the above tabulation = 3.70 percent

Using the above formula:

$$\text{Error} = \frac{(3.70)\sqrt{743.2}}{\sqrt{193.7}}$$

$$= \pm 7.25 \text{ percent}$$

## Survey Procedures

The 1990 Minnesota survey used a growth model-enhanced, two-phase sample design. This sampling scheme and associated estimators are similar to sampling with partial replacement (SPR), in that a set of randomly located plots is available for remeasurement and a random set of new plots is established and measured. A significant feature of the new Minnesota design is stratification for disturbance on the old sample and use of a growth model to improve regression estimates made on old undisturbed forest plots as shown in the following diagram (fig. 5). The growth model used in the Minnesota survey design was the Lake States Stand and Tree Evaluation and Modeling System (STEMS)[2].

[2] *Belcher, David W.; Holdaway, Margaret R.; Brand, Gary J. 1982. A description of STEMS—the Stand and Tree Evaluation and Modeling System. Gen. Tech. Rep. NC-79. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station. 18 p.*

Figure 5.—*Overview of the Minnesota sample design.*

These were the major steps in the new survey design:

1. Aerial photography (Phase 1)

In this phase two sets of random points were located on current aerial photography. The first is a set of new photo plots, and the second is a set of relocated old ground plot locations from the 1977 inventory. Photos were 1:58,000 scale color infrared National High Altitude Photography Program (NHAP) prints purchased by the Minnesota Department of Natural Resources (MDNR) from the U.S. Geological Survey. In addition, MDNR provided 35mm true color prints at a scale of 1:15,840 of all of the 1977 ground plot locations. These 35mm prints were used in addition to the NHAP prints to aid in disturbance detection of the 1977 ground plot locations. The year of photography for each county in the Forest is shown below.

| | Date | |
|---|---|---|
| **County** | **NHAP** | **35mm** |
| Beltrami | 1981-1983 | 1987 |
| Cass | 1981 | 1988 |
| Itasca | 1981 | 1987-1988 |

The locations of the plots used in the 1980 inventory were transferred to these new photographs. The photographs were then assembled into township mosaics, and a systematic grid of 121 one-acre photo plots (each plot representing approximately 190.4 acres) was overlaid on each township mosaic. Each of these photo plots was examined by aerial photogrammetrists and classified stereoscopically, based on land use. If trees were present, forest type and stand size-density class were recorded. All the 1980 ground plot locations were also examined for disturbance (logging, fire, catastrophic mortality, etc.) with the aid of the 35mm photography. After this examination, all the old *"disturbed"* sample locations, a one-third sample of the old *"undisturbed"* sample locations, and a sample of the new photo plots were sent to the field for survey crews to verify the photo classification and to take further measurements. In all, 3,346 new photo plots and 169 ground plot locations from the 1980 inventory were examined for the National Forest and were classified as shown in the tabulation at the top of the next column:

| **Photo land class** | **Photo plots** |
|---|---|
| Timberland | 2,823 |
| Reserved timberland | — |
| Other forest land | 52 |
| Questionable | 50 |
| Nonforest with trees | 40 |
| Nonforest without trees | 364 |
| Water | 17 |
| All classes | 3,346 |

2. Plot measurements (Phase 2)

On plots classified as timberland, wooded pasture, or windbreak (at least 120 feet wide), a ground plot was established, remeasured, or modeled. Each old plot sent to the field for remeasurement that could not be relocated was replaced with a new plot at the approximate location of the old one. Each ground plot consists of a 10-point cluster covering approximately 1 acre. At each point, trees 5.0 inches or more in d.b.h. were sampled on a 37.5 Basal Area Factor (BAF) variable-radius plot, and trees less than 5.0 inches d.b.h. were sampled on a 1/300-acre fixed-radius plot. The measurement procedure for the new and old sample locations was as follows:

a. New inventory plots

A random sample of the new photo plots was selected for field measurement. Ground plots were established, and measures of current classification such as land use, forest type, and ownership as well as the size and condition of all trees on the plot were recorded. These locations were monumented for future remeasurement.

b. Old inventory plots

These plots were established, monumented, and measured as part of the 1980 field inventory. The procedures for these old plot locations were different from those for the new plots. Old plots were classed as *"undisturbed"* or *"disturbed"* in the aerial photo phase sampling process. All disturbed plots and one-third of the undisturbed plots were remeasured to obtain estimates of current condition and changes since the last inventory. All trees measured on these plots in 1980 were remeasured or otherwise accounted for, and all new trees were identified and measured.

All sample plots that were forested at the time of the 1980 inventory and determined to be undisturbed until this inventory were projected to the current time using the Stand and Tree Evaluation and Modeling System (STEMS). This procedure gives projected estimates of current volume and growth for these undisturbed plots. The comparison of the projected and observed values on the one-third sample of the undisturbed forest plots that were remeasured provided local calibration data to adjust the projected values of the undisturbed plots that were not remeasured. The adjustment procedure is a modified version of the method described by Smith[3].

The old sample plots that were not forested in 1980 and that were determined to be undisturbed until the current inventory (no evidence of conversion to another land use) were also subsampled (field checked) at the one-third rate. Any changes in land use to forest detected on these plots were used to adjust the two-thirds sample of these plots not field checked. The field check of these points in the National Forest indicated that no adjustment was necessary.

The undisturbed plots that were not remeasured play a crucial role in the new survey design. These plots, after careful examination comparing past and current aerial photography, were determined to be undisturbed and had conditions that could be simulated by STEMS. The STEMS growth model was used to "grow" the old plot and tree data to produce an estimate of current data. Thus, these plots were treated as ground plots, even though they were never visited. The plot record for each modeled plot was sent to the field for verification of current ownership information.

All old plots classified as disturbed were sent to the field for remeasurement to assess and verify changes since the last inventory. Disturbance refers to any change on a plot that can be detected on aerial photos and that the STEMS growth processor cannot predict, such as catastrophic mortality, cutting, seedling stands, and land use change.

The estimation procedure for computing statistics from this sampling design was more complicated than the simple two-phase estimation procedure used in the past. In fact, this procedure yielded two independent samples, one coming from the new photo points and the other from the old photo points that were remeasured or modeled. The following tabulation summarizes the distribution of all ground plots for the new inventory design by type of plot:

| Ground land use class | Old plots remeasured | Old plots updated | New plots | Total plots |
|---|---|---|---|---|
| Timberland | 149 | 4 | 257 | 410 |
| Reserved forest land | 1 | — | 1 | 2 |
| Other forest land | 2 | 1 | 5 | 8 |
| Nonforest with trees | 3 | — | 2 | 5 |
| Nonforest without trees | 12 | 2 | 34 | 48 |
| Water | 2 | — | 3 | 5 |
| Total | 169 | 7 | 302 | 478 |

[3] *Smith, W. Brad. 1983. Adjusting the STEMS regional growth models to improve local predictions. Res. Note NC-297. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station. 5 p.*

3. Area estimates

The total area of National Forest land was supplied by the Forest staff. Subsequent area estimates were made using two-phase estimation methods. In this type of estimation, a preliminary estimate of area by land use is made from the aerial photographs (Phase 1) and corrected by the plot measurements (Phase 2). A complete description of this estimation method is presented by Loetsch and Haller (1964)[4].

Area estimates within the Chippewa National Forest were determined in the same way as other lands but were verified by comparison with National Forest compartment examination records maintained by the Forest Timber Management Staff. This is an intensive area inventory system in which, over a period of years, each stand in the Forest is mapped on aerial photographs and then classified by ground visits.

4. Volume estimates

Estimates of volume per acre were made from the trees measured or modeled on the 10-point plots. Estimates of volume per acre were multiplied by the area estimates to obtain estimates of total volume. Net cubic foot volumes are based on a modification of the method presented by Hahn[5] for use in the Lake States. For the Minnesota inventory, the merchantable height equation presented was used in conjunction with Stone's equation to estimate gross volume. This estimate was then corrected by species for variation in bark and cull volume to yield an estimate of net volume.

The Forest Service reports all board foot volume in International 1/4-inch rule. In Minnesota, the Scribner log rule is commonly used. Scribner log rule conversion factors were derived from full tree measurements taken throughout the Lake States (Michigan, Wisconsin, and Minnesota) and an equation developed by Wiant and Castenaeda (1977)[6]. The factors (multipliers) used here to convert board foot International volumes to the Scribner rule are shown in the following tabulation:

| D.B.H. (inches) | Scribner rule conversion factor | |
|---|---|---|
| | Softwoods | Hardwoods |
| 9.0-10.9 | 0.7830 | — |
| 11.0-12.9 | .8287 | 0.8317 |
| 13.0-14.9 | .8577 | .8611 |
| 15.0-16.9 | .8784 | .8827 |
| 17.0-18.9 | .8945 | .8999 |
| 19.0-20.9 | .9079 | .9132 |
| 21.0-22.9 | .9168 | .9239 |
| 23.0-24.9 | .9240 | .9325 |
| 25.0-26.9 | .9299 | .9396 |
| 27.0-28.9 | .9321 | .9454 |
| 29.0+ | .9357 | .9544 |

5. Growth and mortality estimates

On remeasured plots, estimates of growth and mortality per acre come from the remeasured diameters of trees and from observation of trees that died between inventories. Growth reported as the average net annual growth between the two inventories (1980 and 1990) is computed from data on remeasurement plots and modeled plots using methods presented by VanDeusen *et al.*[7] Mortality is also average net annual for the remeasurement period. On new plots, where trees were not remeasured, estimates of growth and mortality were obtained by using STEMS to project the growth and mortality of trees for 1 year. Growth and mortality estimates for old undisturbed plots that were updated were derived in the same manner as for remeasured plots. The STEMS growth model was adjusted by Survey Unit to meet local conditions, using data from the undisturbed remeasurement

[5] *Hahn, Jerold T. 1984. Tree volume and biomass equations for the Lake States. Res. Pap. NC-250. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station. 10 p.*

[6] *Wiant, Harry V., Jr.; Castenaeda, Froylan. 1977. Mesavage and Girard's volume tables formulated. BLM4. Denver, CO: U.S. Department of the Interior, Bureau of Land Management, Denver Service Center. 4 p.*

[7] *VanDeusen, P.C.; Dell, T.R.; Thomas, C.E. 1986. Volume growth estimation from permanent horizontal points. Forest Science. 32: 415-422.*

plots. As with volume, total growth and mortality estimates were obtained by multiplying the per acre estimates by area estimates. Current annual growth for 1990 was computed by using the adjusted STEMS model to grow all current inventory plots for 1 year.

6. Average annual removals estimates

Average annual growing-stock and sawtimber removals (1980 to 1990) were estimated only from the remeasured plots; new plots were not used to estimate removals. These estimates are obtained from trees measured in the last survey and cut or otherwise removed from the timberland base. Because remeasurement plots make up about one-half of the total ground plots, average annual removals estimates have greater sampling errors than volume and growth estimates.

## COMPARING MINNESOTA'S FIFTH INVENTORY WITH THE FOURTH INVENTORY

The following paragraphs highlight some of the procedural changes since the last inventory to assist the reader in analyzing data from this report:

A new volume estimation procedure has been developed for the Lake States (see Survey Procedures), and this procedure was used to compute the 1990 volumes and also to recompute the 1980 volume for growth calculations. Although the adjustment will differ by Survey Unit and species, the recomputed 1980 growing-stock and board foot volumes will generally be greater than those reported for 1980.

Mortality figures published in the 1980 inventory report were based on field estimates of the number of trees that died in the 3 years before the inventory. Information gathered on remeasurement plots during the current inventory was used to adjust the 1979 mortality figures. This adjustment will also affect the estimate of net growth for the 1980 inventory.

Past surveys used only growing-stock trees to determine stand-size class. Current survey procedures require that stand-size class be determined on the basis of all live trees. Therefore, direct comparisons of current inventory data to old inventory data by stand-size class may be misleading.

## LOG GRADES

In Minnesota the butt log of every sawtimber sample tree was graded for quality on approximately one-third of the sample plots. The volume yield by log grade for species in this sample was used to distribute the volume of trees in the ungraded sample into log-grade classes by species group.

Logs were graded on the basis of external characteristics as indicators of quality. Hardwood species were graded according to "A guide to hardwood log grading" (1973)[8]. The best 12-foot section of the lowest 16-foot hardwood log, or the best 12-foot upper section if the butt log did not meet minimum log-grade standards, was graded as follows:

---

[8] *Rast, Everette D.; Sonderman, David L.; Gammon, Glenn L. 1973. A guide to hardwood log grading. Gen. Tech. Rep. NE-1. Upper Darby, PA: U.S. Department of Agriculture, Forest Service, Northeastern Forest Experiment Station. 31 p.*

# Forest Service standard grades for hardwood factory saw logs

| Grading Factors | | Specifications | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | Log grade 1 | | | Log grade 2 | | | | Log grade 3 | |
| Position in tree | | Butts only | Butts & uppers | | Butts & uppers | | | | | Butts & uppers |
| Scaling diameter, inches | | 13-15[1] | 16-19 | 20+ | 11+[2] | | 12+ | | | |
| Length without trim, feet | | 10+ | | | 10+ | 8-9 | 10-11 | 12+ | 8+ | |
| Required clear cuttings[3] of each of three best faces[4] | Min. length, feet | 7 | 5 | 3 | 3 | 3 | 3 | 3 | 2 | |
| | Max. number | 2 | 2 | | 2 | 2 | 2 | 3 | No limit | |
| | Min. proportion of log length required in clear cutting | 5/6 | 5/6 | 5/6 | 2/3 | | 3/4 | 2/3 | 2/3 | 1/2 |
| Maximum sweep & crook allowance | For logs with less than one-fourth of end in sound defects | 15 percent | | | 30 percent | | | | | 50 percent |
| | For logs with more than one-fourth of end in sound defects | 10 percent | | | 20 percent | | | | | 35 percent |
| Maximum scaling deduction | | 40 percent[5] | | | 50 percent[6] | | | | | 50 percent |

1 *Ash and basswood butts can be 12 inches if they otherwise meet requirements* for small #1's.
2 *Ten-inch logs of all species can be #2 if they otherwise meet requirements for small #1's.*
3 *A clear cutting is a portion of a face, extending the width of the face, that is free of defects.*
4 *A face is one-fourth of the surface of the log as divided lengthwise.*
5 *Otherwise #1 logs with 41-60 percent deductions can be #2.*
6 *Otherwise #2 logs with 51-60 percent deductions can be #3.*

## Forest Service standard specifications for hardwood construction logs (tie and timber logs)[1]

| | |
|---|---|
| Position in tree | Butts and uppers |
| Min. diameter, small end | 8 inches + |
| Min. length without trim | 8 feet |
| Clear cuttings | No requirements |
| Sweep allowance | One-fourth of the diameter at the small end for each 8 feet of length. |
| Sound surface defects: | |
| Single knots | Any number, if no one knot has an average diameter above the callus in excess of one-third of the log diameter at point of occurrence. |
| Whorled knots | Any number, if the sum of knot diameters above the callus does not exceed one-third of the log diameter at point of occurrence. |
| Holes | Any number, provided none has a diameter over one-third of the log diameter at point of occurrence and none extends more than 3 inches into included timber[2]. |
| Unsound surface defects: | Same requirements as for sound defects if they extend into included timber. No limit if they do not. |

[1] *These specifications are minimum for the class. If, from a group of logs, factory logs are selected first, thus leaving only nonfactory logs from which to select construction logs, then the quality range of the construction logs so selected is limited, and the class may be considered a grade. If selection for construction logs is given first priority, it may be necessary to subdivide the class into grades.*

[2] *Included timber is always square, and dimension is judged from small end.*

## LOG GRADES FOR EASTERN WHITE PINE

| Log grade | Minimum size[1] Diameter | Length | Sweep or crook allowance | Total cull allowance including sweep | Maximum weevil injury | Allowable knot size (inches)[2] on three best faces or minimum clearness on four faces |
|---|---|---|---|---|---|---|
| | *(Inches)* | *(Feet)* | *(Percent)* | *(Percent)* | *(Number)* | *(Inches)* |
| 1 | 12 & 13 | 8-16 | 20 | 50 | 0 | Four faces clear full length |
| | 14+ | 10-16 | 20 | 50 | 0 | Two faces clear full length, or four faces clear 50 percent length (6 feet min. length)[3] |
| 2 | 6+ | 8-16 | 30 | 50 | 0 | Sound knots l.e.[4] D.6 and less than 3 inches[5]<br><br>Unsound knots: l.e. 1-1/2 inches and for: butt, log l.e. D/12 upper logs l.e. D/10, or four faces clear 50 percent of length |
| 3 | 6+ | 8-16 | 40 | 50 | 8-foot logs 1 weevil<br><br>10-foot+ logs: 2 weevils | Sound knots l.e. D/3 and less than 5 inches<br><br>Unsound knots l.e. D/6 and less than 2-1/2 inches |
| 4 | 6+ | 8-16 | 50 | 50 | No limit | No limit |

1 *Plus trim.*

2 *Disregard all knots less than 1/2-inch diameter in all grades.*

3 *The sum of the diameter of sound knots plus twice the sum of the diameter of unsound knots (in inches) is less than or equal to half of the diameter of the log (inches.)*

4 *l.e. means less than or equal to.*

5 *D means d.i.b. of log at location of knot.*

## LOG GRADES FOR JACK PINE AND RED PINE

*Grade 1*: Logs with three or four clear faces.[1]

*Grade 2*: Logs with one or two clear faces.

*Grade 3*: Logs with no clear faces.

After the tentative log grade is established from above, the log will be degraded one grade for each of the following, except that no log can be degraded below grade 3. Net scale after deduction for defect must be at least 50 percent of the gross contents of the log.

1. *Sweep.* Degrade any tentative 1 or 2 log one grade if sweep amounts to 3 or more inches and equals or exceeds one-third of the diameter inside bark at small end.

2. *Heart rot.* Degrade any tentative 1 or 2 log one grade if conk, massed hyphae, or other evidence of advanced heart rot is found anywhere in it.

[1] *A face is one-fourth of the circumference in width extending full length of the log. Clear faces are those free of: knots measuring more than 1/2-inch in diameter, overgrown knots of any size, and holes more than 1/4-inch in diameter. Faces may be rotated to obtain the maximum number of clear ones.*

## LOG GRADES FOR ALL OTHER SOFTWOOD LOGS

*Grade 1*

1. Logs must be 16 inches in diameter or larger, 10 feet in length or longer, and with deduction for defect not over 30 percent of gross scale.

2. Logs must be at least 75 percent clear on each of three faces.

3. All knots outside clear cutting must be sound and not more than 2-1/2 inches in size.

*Grade 2*

1. Logs must be 12 inches in diameter or larger, 10 feet in length or longer, and with a net scale after deduction for defect of at least 50 percent of the gross scale deducted for defect.

2. Logs must be at least 50 percent clear on each of three faces or 75 percent clear on two faces.

*Grade 3*

1. Logs must be 6 inches in diameter or larger, 8 feet in length or longer, and with a net scale after deduction for defect of at least 50 percent of the gross contents of the log.

*Note: A) Diameters are diameter inside bark (d.i.b.) at small end of log.*
*B) Percent clear refers to percent clear in one continuous section.*

## METRIC EQUIVALENTS OF UNITS USED IN THIS REPORT

1 acre = 4,046.86 square meters or 0.405 hectare.
1,000 acres = 405 hectares.
1 cubic foot = 0.0283 cubic meter.
1 foot = 30.48 centimeters or 0.3048 meter.
1 inch = 25.4 millimeters, 2.54 centimeters, or 0.0254 meter.
1 pound = 0.454 kilograms.
1 ton = 0.907 metric tons.

## TREE SPECIES GROUPS ON THE CHIPPEWA NATIONAL FOREST[9]

**SOFTWOODS**

Eastern white pine ..... *Pinus strobus*
Red pine ..... *Pinus resinosa*
Jack pine ..... *Pinus banksiana*
White spruce ..... *Picea glauca*
Black spruce ..... *Picea mariana*
Balsam fir ..... *Abies balsamea*
Tamarack ..... *Larix laricina*
Northern white-cedar ..... *Thuja occidentalis*
Other softwoods:
  Eastern redcedar ..... *Juniperus virginiana*
  Scotch pine ..... *Pinus sylvestris*

**HARDWOODS**

White oak[10]
  White oak ..... *Quercus alba*
  Bur oak ..... *Quercus macrocarpa*
Red oak[10]
  Northern red oak ..... *Quercus rubra*
  Northern pin oak ..... *Quercus ellipsoidalis*
  Black oak ..... *Quercus velutina*
Hickory[10]
  Shagbark hickory ..... *Carya ovata*
  Bitternut hickory ..... *Carya cordiformis*
Hard maple[10]
  Black maple ..... *Acer nigrum*
  Sugar maple ..... *Acer saccharum*
Soft maple[11]
  Red maple ..... *Acer rubrum*
  Silver maple ..... *Acer saccharinum*
Birch
  Paper birch[11] ..... *Betula papyrifera*
  Yellow birch[10] ..... *Betula alleghaniensis*
Ash[10]
  Black ash ..... *Fraxinus nigra*
  Green ash ..... *Fraxinus pennsylvanica*
Balsam poplar[11] ..... *Populus balsamifera*
Aspen[11]
  Bigtooth aspen ..... *Populus grandidentata*
  Quaking aspen ..... *Populus tremuloides*
Cottonwood[11] ..... *Populus deltoides*
Basswood[11] ..... *Tilia americana*
Black walnut[10] ..... *Juglans nigra*
Black cherry[11] ..... *Prunus serotina*
Butternut[11] ..... *Juglans cinerea*
Elm
  American elm[11] ..... *Ulmus americana*
  Slippery elm[11] ..... *Ulmus rubra*
  Rock elm[10] ..... *Ulmus thomasii*
Hackberry[11] ..... *Celtis occidentalis*
Black willow[11] ..... *Salix nigra*
Other hardwoods
  Boxelder[11] ..... *Acer negundo*
  Black locust[10] ..... *Robinia pseudoacacia*
  Red mulberry[11] ..... *Morus rubra*
  Honeylocust[10] ..... *Gleditsia triacanthos*
  Northern catalpa[10] ..... *Catalpa speciosa*
Noncommercial species
  Eastern hophornbeam ..... *Ostrya virginiana*
  Apple ..... *Malus* spp.
  American hornbeam ..... *Carpinus caroliniana*
  Wild plum ..... *Prunus* spp.
  Hawthorn ..... *Crataegus* spp.

[9] *The common and scientific names are based on: Little, Elbert L. 1979. Checklist of native and naturalized trees of the United States. Agric. Handb. 541. Washington, DC: U.S. Department of Agriculture, Forest Service. 385 p.*

[10] *This species or species group is considered a hard hardwood, with an average specific gravity greater than or equal to 0.50.*

[11] *This species or species group is considered a soft hardwood, with an average specific gravity of less than 0.50.*

## DEFINITION OF TERMS

**Average annual removals from growing stock.**—The average net growing-stock volume in growing-stock trees removed annually for forest products (including roundwood products and logging residues) and for other uses (see Other removals). Average annual removals of growing stock are reported for a period of several years (1980 to 1990 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in Appendix).

**Average annual removals from sawtimber.**—The average net board foot sawtimber volume of live sawtimber trees removed annually for forest products (including roundwood products and other uses (see Other removals)). Average annual removals of sawtimber are reported for a period of several years (1980 to 1990 in this report) and are based on information obtained from remeasurement plots (see Survey Procedures in Appendix).

**Commercial species.**—Tree species presently or prospectively suitable for industrial wood products. (Note: Excludes species of typically small size, poor form, or inferior quality such as hophornbeam, mountain maple, and chokecherry).

**Commercial forest land.**—(See Timberland).

**Cord.**—One standard cord is 128 cubic feet of stacked wood, including bark and air space. Cubic feet can be converted to standard cords by dividing by 79.

**Cull.**—Portions of a tree that are unusable for industrial wood products because of rot, missing or dead material, or other defect.

**Diameter class.**—A classification of trees based on diameter outside bark, measured at breast height (d.b.h.). Two-inch diameter classes are commonly used in Forest Inventory and Analysis, with the even inch the approximate midpoint for a class. For example, the 6-inch class includes trees 5.0 through 6.9 inches d.b.h.

**Diameter at breast height (d.b.h.).**—The outside bark diameter at 4.5 feet (1.37m) above the forest floor on the uphill side of the tree. For determining breast height, the forest floor includes the duff layer that may be present, but does not include unincorporated woody debris that may rise above the ground line.

**Forest land.**—Land at least 16.7 percent stocked by forest trees of any size, or formerly having had such tree cover, and not currently developed for nonforest use. (Note: Stocking is measured by comparing specified standards with basal area and/or number of trees, age or size, and spacing.) The minimum area for classification of forest land is 1 acre. Roadside, streamside, and shelterbelt strips of timber must have a crown width of at least 120 feet to qualify as forest land. Unimproved roads and trails, streams, or other bodies of water or clearings in forest areas shall be classed as forest if less than 120 feet wide. (See Tree, Land, Timberland, Reserved forest land, Other forest land, and Stocking.)

**Forest type.**—A classification of forest land based on the species forming a plurality of live tree stocking. Major forest types in the State are:

*Jack pine.*—Forests in which jack pine comprises a plurality of the stocking. (Common associates include eastern white pine, red pine, aspen, birch, and maple.)

*Red pine.*—Forests in which red pine comprises a plurality of the stocking. (Common associates include eastern white pine, jack pine, aspen, birch, and maple.)

*White pine.*—Forests in which eastern white pine comprises a plurality of the stocking. (Common associates include red pine, jack pine, aspen, birch, and maple.)

*Balsam fir.*—Forests in which balsam fir and white spruce comprise a plurality of the stocking with balsam fir the most common. (Common associates include aspen, maple, birch, northern white-cedar, and tamarack.)

*White spruce.*—Forests in which white spruce and balsam fir comprise a plurality of the stocking with white spruce the most common. (Common associates include aspen, maple, birch, northern white-cedar, and tamarack.)

*Black spruce.*—Forests in which swamp conifers comprise a plurality of the stocking with black spruce the most common. (Common associates include tamarack and northern white-cedar.)

*Northern white-cedar.*—Forests in which swamp conifers comprise a plurality of the stocking with northern white-cedar the most common. (Common associates include tamarack and black spruce.)

*Tamarack.*—Forests in which swamp conifers comprise a plurality of the stocking with tamarack the most common. (Common associates include black spruce and northern white-cedar.)

*Oak-hickory.*—Forests in which oaks or hickories, singly or in combination, comprise a plurality of the stocking. (Common associates include jack pine, elm, and maple.)

*Elm-ash-soft maple.*—Forests in which lowland elm, ash, red maple, silver maple, and cottonwood, singly or in combination, comprise a plurality of the stocking. (Common associates include birches, spruce, and balsam fir.)

*Maple-basswood.*—Forests in which sugar maple, basswood, yellow birch, upland American elm, and red maple, singly or in combination, comprise a plurality of the stocking. (Common associates include white pine, elm, and basswood.)

*Aspen.*—Forests in which quaking aspen or bigtooth aspen, singly or in combination,

comprise a plurality of the stocking. (Common associates include balsam poplar, balsam fir, and paper birch.)

*Paper birch.*—Forests in which paper birch comprises a plurality of the stocking. (Common associates include maple, aspen, and balsam fir.)

*Balsam poplar.*—Forests in which balsam poplar comprised a plurality of the stocking. (Common associates include aspen, elm, and ash.)

**Growing-stock tree.**—A live tree of commercial species that meets specified standards of size, quality, and merchantability. (Note: Excludes rough, rotten, and dead trees.)

**Growing-stock volume.**—Net volume in cubic feet of growing-stock trees 5.0 inches d.b.h. and over, from 1 foot above the ground to a minimum 4.0 inch top diameter outside bark of the central stem or to the point where the central stem breaks into limbs.

**Hard hardwoods.**—Hardwood species with an average specific gravity greater than 0.50 such as oaks, hard maple, hickories, and ash.

**Hardwoods.**—Dicotyledonous trees, usually broad-leaved and deciduous. (See Soft hardwoods and Hard hardwoods.)

**Land.**—*A. Bureau of the Census.* Dry land and land temporarily or partly covered by water such as marshes, swamps, and river flood plains (omitting tidal flats below mean high tide); streams, sloughs, estuaries, and canals less than one-eighth of a statute mile wide; and lakes, reservoirs, and ponds less than 40 acres in area.

*B. Forest Inventory and Analysis.* The same as the Bureau of the Census, except minimum width of streams, etc., is 120 feet and minimum size of lakes, etc., is 1 acre.

**Log grade.**—A log classification based on external characteristics as indicators of quality or value. (See Appendix for specific grading factors used.)

**Marsh.**—Nonforest land that characteristically supports low, generally herbaceous or shrubby vegetation and that is intermittently covered with water.

**Merchantable.**—Refers to a pulpwood or saw-log section that meets pulpwood or saw-log specifications, respectively.

**Mortality.**—The volume of sound wood in growing-stock and sawtimber trees that die annually.

**National Forest land.**—Federal land that has been legally designated as National Forest or purchase units, and other land administered by the USDA Forest Service.

**Net annual growth of growing stock.**—The annual change in volume of sound wood in live sawtimber and poletimber trees and the total volume of trees entering these classes through ingrowth, less volume losses resulting from natural causes.

**Net annual growth of sawtimber.**—The annual change in the volume of live sawtimber trees and the total volume of trees reaching sawtimber size, less volume losses resulting from natural causes.

**Net volume.**—Gross volume less deductions for rot, sweep, or other defect affecting use for timber products.

**Noncommercial species.**—Tree species of typically small size, poor form, or inferior quality that normally do not develop into trees suitable for industrial wood products.

**Nonforest land.**—Land that has never supported forests, and land formerly forested where use for timber management is precluded by development for other uses. (Note: Includes areas used for crops, improved pasture, residential areas, city parks, improved roads of any width and adjoining clearings, powerline clearings of any width, and 1- to 40-acre areas of water classified by the Bureau of the Census as land. If intermingled in forest areas, unimproved roads and nonforest strips must be more than 120 feet wide and more than 1 acre in area to qualify as nonforest land.)

*a. Nonforest land without trees.*—Nonforest land with no live trees present.

*b. Nonforest land with trees.*—Nonforest land with one or more trees per acre at least 5 inches d.b.h.

**Nonstocked land.**—Forest land less than 16.7 percent stocked with all live trees.

**Other forest land.**—Forest land not capable of producing 20 cubic feet per acre per year of industrial wood crops under natural conditions and not associated with urban or rural development. These sites often contain tree species that are not currently utilized for industrial wood production or trees of poor form, small size, or inferior quality that are unfit for industrial products. Unproductivity may be the result of adverse site conditions such as sterile soil, dry climate, poor drainage, high elevation, and rockiness. This land is not withdrawn from timber utilization.

**Other removals.**—Growing-stock trees removed but not utilized for products, or trees left standing but "removed" from the timberland classification by land use change. Examples are removals from cultural operations such as timber stand improvement work, land clearing, and changes in land use.

**Poletimber stand.**—(See Stand-size class.)

**Poletimber tree.**—A growing-stock tree of commercial species at least 5.0 inches d.b.h. but smaller than sawtimber size.

**Reserved forest land.**—Forest land withdrawn from timber utilization through statute, administrative regulation, designation, or exclusive use for Christmas tree production, as indicated by annual shearing.

**Rotten tree.**—A tree that does not meet regional merchantability standards because of excessive unsound cull. May include noncommercial tree species.

**Rough tree.**—A tree that does not meet regional merchantability standards because of excessive sound cull. May include noncommercial tree species.

**Salvable dead tree.**—A standing or down dead tree considered merchantable by regional standards.

**Sapling.**—A live tree 1.0 to 5.0 inches d.b.h.

**Sapling-seedling stand.**—(See Stand-size class.)

**Saw log.**—A log meeting minimum standards of diameter, length, and defect, including logs at least 8 feet long, sound and straight and with a minimum diameter outside bark (d.o.b.) for softwoods of 7.0 inches (9.0 inches for hardwoods) or other combinations of size and defect specified by regional standards.

**Saw-log portion.**—That part of the bole of sawtimber trees between the stump and the saw-log top.

**Saw-log top.**—The point on the bole of sawtimber trees above which a saw log cannot be produced. The minimum saw-log top is 7.0 inches d.o.b. for softwoods and 9.0 inches d.o.b. for hardwoods.

**Sawtimber stand.**—(See Stand-size class.)

**Sawtimber tree.**—A growing-stock tree of commercial species containing at least a 12-foot saw log or two noncontiguous saw logs 8 feet or longer, and meeting regional specifications for freedom from defect. Softwoods must be at least 9.0 inches d.b.h. Hardwoods must be at least 11.0 inches d.b.h.

**Sawtimber volume.**—Net volume of the saw-log portion of live sawtimber in board feet, International 1/4-inch rule (unless specified otherwise) from stump to a minimum 7 inches top diameter outside bark (d.o.b.) for softwoods and a minimum 9 inches top d.o.b. for hardwoods.

**Seedling.**—A live tree less than 1.0 inch d.b.h. that is expected to survive. Only softwood seedlings more than 6 inches tall and hardwood seedlings more than 1 foot tall are counted.

**Short-log (rough tree).**—Sawtimber-size trees of commercial species that contain at least one merchantable 8- to 11-foot saw log but not a 12-foot saw log.

**Site class.**—A classification of forest lands in terms of inherent capacity to grow crops of industrial wood. The class identifies the potential growth in merchantable cubic feet/acre/year at culmination of mean annual increment of fully stocked natural stands.

**Site index**.—An expression of forest site quality based on the height of a free-growing dominant or codominant tree of a representative species in the forest type at age 50.

**Soft hardwoods**.—Hardwood species with an average specific gravity less than 0.50 such as gum, yellow-poplar, cottonwood, red maple, basswood, and willow.

**Softwoods**.—Coniferous trees, usually evergreen, having needles or scale-like leaves.

**Stand**.—A group of trees on a minimum of 1 acre of forest land that is stocked by forest trees of any size.

**Stand-size class**.—A classification of stocked (see Stocking) forest land based on the size class of live trees on the area; that is, sawtimber, poletimber, or saplings and seedlings.

*a. Sawtimber stands*.—Stands with half or more of live stocking in sawtimber or poletimber trees, and with sawtimber stocking at least equal to poletimber stocking.

*b. Poletimber stands*.—Stands with half or more live stocking in poletimber and/or sawtimber trees, and with poletimber stocking exceeding that of sawtimber.

*c. Sapling-seedling stands*.—Stands with more than half of the live stocking in saplings and/or seedlings.

**Stocking**.—The degree of occupancy of land by live trees, measured by basal area and/or the number of trees in a stand by size or age and spacing, compared to the basal area and/or number of trees required to fully utilize the growth potential of the land; that is, the stocking standard.

A stocking percent of 100 indicates full utilization of the site and is equivalent to 80 square feet of basal area per acre in trees 5.0 inches d.b.h. and larger. In a stand of trees less than 5 inches d.b.h., a stocking percent of 100 would indicate that the present number of trees is sufficient to produce 80 square feet of basal area per acre when the trees reach 5 inches d.b.h.

Stands are grouped into the following stocking classes:

*Overstocked stands*.—Stands in which stocking of live trees is 133 percent or more.

*Fully stocked stands*.—Stands in which stocking of live trees is from 100.0 to 132.9 percent.

*Medium stocked stands*.—Stands in which stocking of live trees is from 60.0 to 99.9 percent.

*Poorly stocked stands*.—Stands in which stocking of live trees is from 16.7 to 59.9 percent.

*Nonstocked areas*.—Timberland on which stocking of live trees is less than 16.7 percent.

**Timberland**.—Forest land that is producing or capable of producing in excess of 20 cubic feet per acre per year of industrial wood crops under natural conditions, that is not withdrawn from timber utilization, and that is not associated with urban or rural development. Currently inaccessible and inoperable areas are included (formerly commercial forest land).

**Tree**.—A woody plant usually having one or more perennial stems, a more or less definitely formed crown of foliage, and a height of at least 12 feet at maturity.

**Tree size class**.—A classification of trees based on diameter at breast height, including sawtimber trees, poletimber trees, saplings, and seedlings.

**Upper stem portion**.—That part of the bole of sawtimber trees above the saw-log top to a minimum top diameter of 4.0 inches outside bark or to the point where the central stem breaks into limbs.

**Wooded strip**.—An acre or more of natural continuous forest land that would otherwise meet survey standards for timberland except that it is less than 120 feet wide.

Table 5.--Area of timberland by forest type and stocking class of growing-stock trees[1], Chippewa National Forest, 1990

(In thousand acres)

| Forest type | All classes | Stocking percent of growing-stock trees Non-stocked | Poorly stocked | Moderately stocked | Fully stocked | Over-stocked |
|---|---|---|---|---|---|---|
| Jack pine | 11.7 | -- | -- | 2.5 | 4.5 | 4.7 |
| Red pine | 51.3 | -- | -- | 9.0 | 11.8 | 30.5 |
| White pine | 4.0 | -- | -- | 1.3 | 1.1 | 1.6 |
| Balsam fir | 23.6 | -- | 2.5 | 7.4 | 12.5 | 1.2 |
| White spruce | 4.9 | -- | 3.5 | -- | 1.4 | -- |
| Black spruce | 37.5 | 1.2 | -- | 5.2 | 17.1 | 14.0 |
| Northern white-cedar | 26.0 | -- | 1.5 | 8.9 | 11.1 | 4.5 |
| Tamarack | 22.6 | -- | 7.1 | 9.6 | 3.9 | 2.0 |
| Oak-hickory | 7.2 | 1.2 | -- | 2.3 | 3.7 | -- |
| Elm-ash-soft maple | 33.8 | -- | 6.2 | 15.5 | 10.7 | 1.4 |
| Maple-basswood | 55.4 | -- | 2.3 | 20.7 | 26.2 | 6.2 |
| Aspen | 238.6 | -- | 12.4 | 51.2 | 106.0 | 69.0 |
| Paper birch | 34.8 | -- | 8.4 | 12.7 | 9.5 | 4.2 |
| Balsam poplar | 15.8 | -- | -- | 11.1 | 4.7 | -- |
| All types | 567.2 | 2.4 | 43.9 | 157.4 | 224.2 | 139.3 |

[1] This table is based on the stocking percent of growing-stock trees rather than that of all live trees. To use the definitions of stocking for this table, replace the term "all live" by "growing-stock."

Table 6.--Number of all live trees on timberland by species group and diameter class, Chippewa National Forest, 1990

(In thousand trees)

| Species group | All classes | Diameter class (inches at breast height) 1.0-2.9 | 3.0-4.9 | 5.0-6.9 | 7.0-8.9 | 9.0-10.9 | 11.0-12.9 | 13.0-14.9 | 15.0-16.9 | 17.0-18.9 | 19.0-20.9 | 21.0-28.9 | 29.0+ |

Kingsley, Neal P.; Brittain, Robert E.
1994. **The timber resource of the Chippewa National Forest**. Resour. Bull. NC-156. St. Paul, MN: U.S. Department of Agriculture, Forest Service, North Central Forest Experiment Station. 30 p.

Presents highlights and statistics on area, volume, growth, removals, and mortality from the 1990 forest inventory of the Chippewa National Forest.

KEY WORDS: Area, volume, growth, removals, mortality.

Our job at the North Central Forest Experiment Station is discovering and creating new knowledge and technology in the field of natural resources and conveying this information to the people who can use it. As a new generation of forests emerges in our region, managers are confronted with two unique challenges: (1) Dealing with the great diversity in composition, quality, and ownership of the forests, and (2) Reconciling the conflicting demands of the people who use them. Helping the forest manager meet these challenges while protecting the environment is what research at North Central is all about.
